

# Automation Testing Notes

## 1. Arrow Function

Arrow functions are written using the `=>` operator.

Example:

```
const demo = () => {  
  
}
```

An arrow function can have different kinds of parameters.

### a) String Type Parameter

```
const display = (name: string) => {  
  
}
```

Here,

- `name` → Parameter
- `string` → Data Type

---

### b) Function Type (Callback Function)

Functions can also be passed as parameters.

Example:

```
test("Login Test", async ({ page }) => {  
  
});
```

Here, `test()` receives a **callback function** as its second parameter.

Playwright executes this callback during test execution.

---

## 2. Sprint Level Activity

During a sprint, the **Manual Tester / Functional Tester** performs testing on the newly developed features.

### Activities

- Verify newly developed functionality.
  - Perform Smoke Testing.
  - Perform Sanity Testing.
  - Perform Functional Testing.
  - Check whether the feature is working according to the requirements.
  - Report bugs if any issues are found.
  - Once the feature is stable, identify the test cases suitable for automation.
  - Add stable test cases to the Automation Regression Suite.
- 

## 3. Automation Engineer Activity

After receiving stable test cases from the manual testing team:

- Develop automation scripts.
  - Execute the automation scripts.
  - Verify whether the scripts pass successfully.
  - Fix any script issues if they are caused by automation.
  - Commit the automation code to the repository.
  - Add the scripts to the Regression Suite.
- 

## 4. Regression Testing

Regression Testing is performed to ensure that **existing functionality is not affected by new changes**.

### Activities

- Execute all regression test cases.
  - Verify that existing features continue to work correctly.
  - Validate both old and newly added functionalities.
  - Generate execution reports.
  - Identify failed test cases.
-

## 5. If Automation Test Cases Fail

When automation scripts fail:

### Step 1

Check whether the failure is caused by:

- Locator changes
- Timing issues
- Script issues
- Test data issues
- Environment issues

If yes,

✅ Fix the automation script and execute it again.

---

### Step 2

If the automation script is correct but the application still fails,

- Reproduce the issue manually.
  - Collect evidence (screenshots, logs, videos).
  - Confirm it is an application defect.
- 

### Step 3

If it is an application defect,

- Raise a bug in the defect tracking tool (Jira, Azure DevOps, etc.).
  - Assign the bug to the developer.
  - Provide detailed reproduction steps.
  - Attach logs and screenshots.
- 

### Step 4

After the developer fixes the issue,

- Verify the fix.
- Re-run the automation scripts.
- Confirm that all test cases pass.
- Close the bug if everything works as expected.

# Complete Testing Flow
